Light Scattering By Small Particles

Light scattering by particles is the process by which small particles (e.g. ice crystals, dust, atmospheric particulates, cosmic dust, and blood cells) scatter light causing optical phenomena such as rainbows, the blue color of the sky, and halos.

Light scattering by particles - Wikipedia

The measurement of light scattering of independent, homogeneous particles has many useful applications in physical chemistry, meteorology and astronomy. There is, however, a sizeable gap between the abstract formulae related to electromagnetic-wave-scattering phenomena, and the computation of reliable figures and curves.

For small particle concentration, the intensity of scattered light is a linear function of the particle concentration, as long as a number of other parameters are kept constant: the refractive indexes of the particles and the surrounding medium, size, measuring angle and wavelength of the light.

Rayleigh scattering (pronounced / ' r eɪ l i / RAY-lee), named after the British physicist Lord Rayleigh (John William Strutt), [1] is the predominantly elastic scattering of light or other electromagnetic radiation by particles much smaller than the wavelength of the radiation. Rayleigh scattering does not change the state of material and is, hence, a parametric process.

Traditional visual methods of observing virus particles in solution give a snapshot of only a very small and potentially unrepresentative sampling volume. By comparison, the technique of particle analysis using dynamic light scattering yields an ensemble average of particles present in these solutions.

Analysis of virus particles by Dynamic Light Scattering

DLS cannot, however, quantify the sizes of aggregated particles with radii greater than $\sim 5 \mu\text{m}$; these large sizes require a different characterization technique. DLS also cannot be used to count particles, although complementary light scattering techniques, such as SEC-MALS and FFF-MALS, can provide particle density values.

Rayleigh scattering is a process in which electromagnetic radiation (including light) is scattered by a small spherical volume of variant refractive indexes, such as a particle, bubble, droplet, or even a density fluctuation. This effect was first modeled successfully by Lord Rayleigh, from whom it gets its name.

Scattering experiments were rare in physics before quantum mechanics, except perhaps in relation to the scattering of light by colloids and density fluctuations. After quantum mechanics, scattering experiments became the principal method for the study of atoms, molecules and nuclei, since the properties of the scattering system were reflected ...
