When samples aren't randomly selected, the data usually has some form of bias, so using data that wasn't randomly selected to make inferences about its population can be risky. More specifically, sample proportions are unbiased estimators of their population proportion. For example, if we have a bag of candy where 50% 50%

The observed difference in sample proportions = $\hat{p} - p = 0.587 - 0.650 = -0.063$, so the 95% confidence interval is -0.063 ± 0.1029 , or -16.6% to 4.0%. We are 95% confident that the proportion of women who exercise regularly is between 4.0% lower and 16.6% higher than the proportion of men who exercise regularly.
